

Python testing trial

- You have a variable “x” which is of integer type, such as you can say x=10, convert the “x” integer into float value.
- You have a variable named “a” which is of float type, such as you can say a=12.7, convert that variable type from float to integer such that you will attain lower value and then separately print the upper value.
- Convert any integer value into string value.
- Create a function in python and give it an argument of “x” and call the function by giving it a value.

- Detect an error;

```
def my_function():  
    print("Hello!")
```

- Again, detect an error;

```
def another_function():  
print("Indentation error!")
```

- Detect errors;

```
my_list = [1, 2, 3]  
print(my_list[3])
```

Also, for this;

```
my_dict = {"key": "value"}  
print(my_dict["nonexistent_key"])
```

- If I have a string value such as;

```
txt = 'My roll no is 100 in class.'
```

Use this string value, and extract 100 from this string using regEx “re”.

- Install selenium in jupyter notebook and attach a screenshot as the output.
- Uninstall selenium in jupyter notebook and attach a screenshot as the output.
